2018 Clinical Practice Guidelines
Diabetes and Driving
Diabetes Canada Clinical Practice Guidelines Expert Committee
Robyn L. Houlden MD, FRCP, Lori Berard RN, CDE, Joshua M. Lakoff MD, FRCP, Vincent Woo MD, FRCP, Jean-François Yale MD, CSPQ, FRCP

**KEY MESSAGES**
- The fitness of people with diabetes to drive should be assessed on an individual basis.
- All drivers with diabetes should undergo a medical examination at least every 2 years to assess fitness to drive. Commercial drivers should undergo an assessment at the time of application for a commercial license and as per provincial requirements thereafter.
- People with diabetes should play an active role in assessing their fitness to drive.
- Health-care professionals should educate people with diabetes about strategies to reduce their risks for hypoglycemia while driving. They should also identify and inform individuals with diabetes at higher risk for motor vehicle accidents.

**KEY MESSAGES FOR PEOPLE WITH DIABETES**
- If you take insulin and/or an insulin secretagogue and intend to drive:
  - Consider measuring your blood glucose level immediately before driving, always keep an emergency supply of fast-acting carbohydrate, such as dextrose tablets, within easy reach inside the vehicle and carry your glucose meter and supplies.
  - Consider measuring your blood glucose level immediately before driving, if you develop symptoms of hypoglycemia, and at least every 4 hours while driving. You can also wear a real-time continuous blood glucose monitoring device.
  - Consider measuring your blood glucose more frequently if there are factors that may increase your risk of hypoglycemia, such as recent physical activity or a delay in eating or skipping a meal.
  - If you have a history of recurrent severe hypoglycemic episodes (i.e. associated with loss of consciousness or needing help from another person) or have hypoglycemia unawareness (lack of early warning symptoms of hypoglycemia, such as tremor, sweat, and palpitations), you must measure your blood glucose immediately before and at least every 2 hours while driving or wear a real-time continuous blood glucose monitoring device.
  - Do not start driving if your blood glucose level is less than 4 mmol/L.
  - If your blood glucose is less than 4 mmol/L, do not start driving until you have ingested 15 grams of carbohydrate, you have retested and your blood glucose is at least 5 mmol/L. It is suggested to wait for 40 minutes as it takes time for judgment and reflexes to return.
  - If hypoglycemia develops while driving, stop the vehicle in a safe location and remove the keys from the ignition. Treat low blood glucose and consider waiting 40 minutes before driving.
  - On longer journeys, take regular meals, snacks and periods of rest.
- Immediately notify your health-care provider and your driving licensing body if you experience any episode of severe hypoglycemia while driving or you experience more than 1 episode of severe hypoglycemia while awake but not driving in the past 6 months if you are a private driver, or in the past 12 months if you are a commercial driver.

**Introduction**

For many Canadians, driving is an essential part of daily living and is often a requirement of employment. Diabetes can affect driving performance because of chronic complications which impair sensory or motor function (retinopathy, neuropathy, amputation, vascular disease), and because of transient cognitive dysfunction or loss of consciousness from antihyperglycemic medication-induced hypoglycemia (primarily related to insulin or insulin secretagogues). In addition, other medical disorders associated with type 2 diabetes, such as sleep apnea, can have an adverse impact on driving performance. As the presence and extent of these factors vary from person to person, the fitness of people with diabetes to drive should be assessed on an individual basis as per provincial regulations.

**Driving Risks Associated with Diabetes**

Case-control studies have suggested that drivers with diabetes pose a modestly increased but acceptable and measurable risk of motor vehicle accidents compared to drivers without diabetes, but many studies are limited and of poor quality (1,2). Older studies may no longer be as relevant due to changes in road conditions, vehicles and diabetes management (3).

Unrecognized hypoglycemia is the most relevant driving hazard for drivers with diabetes. A number of studies have examined driving performance with a driving simulator during induced hypoglycemia in individuals with type 1 and 2 diabetes (4). Studies in type 1 diabetes have demonstrated that performance starts to deteriorate at blood glucose (BG) levels below 3.8 mmol/L (5,6). In one study, only 30% of drivers self-treated their low BG, and the treatment occurred only when the BG was ≤2.8 mmol/L (5). Fewer than 25% were aware that their driving performance was impaired (5). The ability of deciding when it is safe to drive may be unreliable or absent in those with hypoglycemia unawareness. During a driving simulator
study, only 4% of those with normal hypoglycemia awareness stated that they would drive while hypoglycemic compared to 43% with impaired awareness of hypoglycemia (5). Studies have demonstrated that cognitive function may not recover until 40 minutes or more after restoration of euglycemia (7–10).

Hypoglycemia is not a problem for drivers with diabetes treated with noninsulin antihyperglycemic medications (diet and physical activity) alone, nor is it a problem for drivers with diabetes treated with most noninsulin antihyperglycemic medications, when used as monotherapy or in combination with each other. Treatment with insulin secretagogues (sulfonylureas, meglitinides) may provoke higher rates of hypoglycemia when used alone or in combination with other noninsulin antihyperglycemic medications (11), including the elderly (12) (see Hypoglycemia chapter, p. S104; Pharmacologic Glycemic Management of Type 2 Diabetes in Adults chapter, p. S88; Diabetes in Older People chapter, p. S283). Studies of rates of motor vehicle accidents in drivers with diabetes have consistently described the highest rates for individuals treated with insulin (12–16).

Factors that have been shown to increase driving risk include previous episodes of severe hypoglycemia within the past 2 years (17–19) with a greater risk in those with lower glycated hemoglobin (A1C) (17,20), previous hypoglycemia while driving (17) and absence of BG monitoring before driving (13,17). Studies have not specifically addressed differences between episodes during waking hours and while asleep. Impaired awareness of hypoglycemia is also a significant risk factor for severe hypoglycemia (19). There is evidence that driving itself is associated with significant metabolic demand and may cause BG to fall (21). These risks may be mitigated by frequent BG testing (22) or use of a real-time continuous glucose monitoring (CGM) device (23). Use of a memory glucose meter is recommended so that measurements can be assessed by the health-care team and by driving authorities, if indicated.

An 11-item questionnaire attempted to identify the at-risk drivers with diabetes (24). Those scoring in the upper quartile reported more driving mishaps than those in the lower quartile. The most discriminating questions regarding accident risk were those that quantified annual mileage, identified a history of hypoglycemia-related vehicle collision, elicited poor self-management of hypoglycemic episodes and screened for the presence of lower limb neuropathy. An Internet-based management program undertaken by drivers with type 1 diabetes reduced the frequency of driving mishaps in high-risk drivers (25).

There are limited data concerning the effects of hyperglycemia on driving, which may depend on how hyperglycemia is defined. In 1 questionnaire-based study, 8% of participants with type 1 diabetes and 40% with type 2 diabetes reported at least 1 episode of disrupted driving associated with hyperglycemia over 1 year (24). No studies have examined the effect of hyperglycemia on driving performance.

### Commercial Driving

The risk for commercial vehicle drivers is higher than that for private drivers as the former are on the road many hours of the day or night, thus increasing their time exposure. The consequences of a motor vehicle accident involving a commercial vehicle are also likely to be more serious, particularly if the vehicle carries passengers or dangerous goods. Therefore, higher medical standards are applied for all commercial vehicle drivers (26).

### Roles and Responsibilities of the Driver with Diabetes and the Health-Care Provider

People with diabetes should play an active role in assessing their own fitness to drive and should have a duty to report conditions that may potentially impair their ability to drive safely, such as hypoglycemia unawareness and episodes of severe hypoglycemia while driving or while awake but not driving. However, studies have demonstrated limited patient awareness of and adherence to recommendations for safe driving. As few as 15% of adults routinely perform self-monitoring of blood glucose (SMBG) before driving (22,27). A survey in Edinburgh of 202 drivers with insulin-treated diabetes showed only 50% of drivers reported following minimum safe driving recommendations: carrying carbohydrate in the vehicle, measuring glucose before a journey, stopping the vehicle during a hypoglycemic episode and recognizing a low glucose as unsafe to drive (22).

Health-care providers play a critical role in educating people with diabetes on strategies to reduce their risk of hypoglycemia while driving. However, many drivers with diabetes receive little or no advice. In a large multinational study, only 52% of drivers with type 1 diabetes and 27% with type 2 diabetes had discussed driving guidelines with their physician (13). Many health-care professionals have deficiencies in their knowledge about the problems associated with diabetes and driving and how these should be minimized (28). In a Scottish study, only 62% of health-care professionals suggested that insulin-treated drivers should test their blood glucose before driving and 8% did not know that impaired glucose awareness might be a contraindication to driving (27). A study in Finland indicated that among private and commercial drivers treated with insulin with self-reported recurrent severe hypoglycemia, 68% continued to hold a valid driving licence (28).

### Mandatory Reporting

Currently, 10 Canadian provinces and territories have a mandatory reporting system obliging legally qualified medical practitioners to report to the appropriate regulatory body those people who have conditions that impair their driving ability (29) (Table 1). Federal organizations, such as the Canadian Council of Motor Transport Administrators (CCMTA), should have consistent, clear and easily accessible reporting mechanisms for physicians and nurse practitioners; in addition, provincial and territorial ministries of transportation should include information on their websites about diabetes and driving, and which types of people with diabetes should be reported. A study in Ontario showed that a program of medical warnings issued to 100,075 people over a 3-year period for a variety of different medical issues, including alcoholism, epilepsy, dementia, sleep disorders and diabetes, resulted in a 45% reduction in

RECOMMENDATIONS

1. Fitness of people with diabetes to drive should be assessed on an individual basis [Grade D, Consensus]. People with diabetes should take an active role in assessing their ability to drive safely.

2. All drivers with diabetes should undergo a comprehensive medical examination at least every 2 years by a physician/nurse practitioner competent in managing people with diabetes. The medical examination should include an assessment of glycemic control; frequency and severity of hypoglycemia; symptomatic awareness of hypoglycemia; and the presence of retinopathy, neuropathy, nephropathy, amputation and CV disease, to identify whether any of these factors could significantly increase the risk of a motor vehicle accident [Grade D, Consensus]. Commercial drivers should also undergo a medical examination at the time of application for a commercial license [Grade D, Consensus].

3. Drivers with diabetes treated with insulin secretagogues and/or insulin:
   a. Should maintain a log of their SMBG measurements either by using a memory-equipped BG meter or electronic record of BG measurement performed at a frequency deemed appropriate by the person with diabetes and their health-care team. For commercial drivers, for initial commercial licence application, the record should include the last 6 months (or since the diagnosis of diabetes if less than 6 months). BG logs should be verifiable on request [Grade D, Consensus].
   b. Should always have BG monitoring equipment and supplies of rapidly absorbed carbohydrate within easy reach (e.g., attached to the driver’s side visor or in the centre console) [Grade D, Consensus].
   c. Should consider measuring their BG level immediately before and at least every 4 hours while driving or wear a real-time CGM device [Grade D, Consensus].
   d. Should not drive when their BG level is <4.0 mmol/L [Grade C, Level 3 (5) for type 1 diabetes; Grade D, Consensus for type 2 diabetes]. If the BG level is <4.0 mmol/L, they should not drive until at least 40 minutes after successful treatment of hypoglycemia has increased their BG level to at least 5.0 mmol/L [Grade C, Level 3 (10) for type 1 diabetes; Grade D, Consensus for type 2 diabetes].
   e. Must refrain from driving immediately if they experience severe hypoglycemia while driving, and notify their health-care provider as soon as possible (no longer than 72 hours) [Grade D, Consensus].

4. Private and commercial drivers with diabetes and hypoglycemia unawareness or history of severe hypoglycemia in the past 12 months must measure their BG level immediately before and at least every 2 hours while driving or wear a real-time CGM device [Grade D, Consensus].

5. If any of the following occur, health-care professionals should inform people with diabetes treated with insulin secretagogues and/or insulin to no longer drive, and should report their concerns about the person’s fitness to drive to the appropriate driving licensing body:
   a. Any episode of severe hypoglycemia while driving in the past 12 months [Grade D, Consensus].
   b. More than 1 episode of severe hypoglycemia while awake but not driving in the past 6 months for private drivers, and in the past 12 months for commercial drivers [Grade D, Consensus].
